

Examination: Derivatives (1928)

Summer Term 2006

Examiner: Prof. Dr. Peter Reichling

The following aids can be used: non-programmable pocket calculator, English language dictionary without any marking

This examination comprises **4 problems** (on 3 pages). All of the problems are to be solved.

EXAMINATION QUESTIONS:

Problem 1. (12 Points)

- (a) With the help of an arbitrage table derive the lower bound for a European call option on a non-dividend paying stock.
- (b) Consider two options on the same underlying with the same expiration day but different exercise prices. What relationship should hold in case of European call options? Show it with the help of an arbitrage table!
- (c) Construct an arbitrage table for a synthetic call. (*Hint:* Here the put-call parity might be useful.)

Problem 2. (15 Points)

Consider a one-period binomial model in which the underlying is at 65 and can go up 30 percent or down 22 percent. The risk-free rate is 8 percent.

- (a) Determine the price of a European call option with exercise price of 70.
- (b) Assume that the call is selling for 9 in the market. Demonstrate how to execute an arbitrage transaction and calculate the rate of return. Use 10,000 call options.

Problem 3. (15 Points)

- (a) What are the assumptions of the Black-Scholes model? (*Note:* Name at least six of them.) Which one of these assumptions is the most critical.
- (b) How can one interpret $N(d_2)$ from the Black-Scholes formula?
- (c) What is implied volatility? Under what conditions, is the implied volatility an unreliable value?
- (d) What does the risk-neutral valuation mean in the Black-Scholes world?

Problem 4. (18 Points)

A fund manager has a well-diversified portfolio that mirrors the performance of the S&P 500 and is worth \$360 million. The value of the S&P 500 is 1,200, and the portfolio manager would like to buy an insurance against a reduction of more than 5% in the value of the

portfolio over the next six months. The risk-free interest rate is 6% per annum. The volatility of the index is 30% per annum.

- (a) How many European put options would the fund manager require, and what strike price should this option have? (*Hint: Here you should just carefully consider the insurance strategy of the fund manager!*)
- (b) If the fund manager buys traded European put options, how much would the insurance cost?
- (c) Explain carefully alternative strategies open to the fund manager involving traded European call options, and show that they lead to the same result. (*Note: Computation of a call option price is not required.*)
- (d) If the fund manager decides to provide an insurance by keeping part of the portfolio in risk-free securities, what should the initial position be?

Cumulative Probabilities for a Standard Normal Distribution

$P(Z \leq x) = N(x)$ for $x \geq 0$ or $P(Z \leq z) = N(z)$ for $z \geq 0$

z =	0.00	0.01	0.02	0.03	0.04	0.05	0.06	0.07	0.08	0.09

3.90	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000
4.00	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000

For example, to find the z-value leaving 2.5% of the area/probability in the upper tail, find 0.9750 in the body of the table.

Read 1.90 at the left end of the row and 0.06 at the top of the column, to give $1.90 + 0.06 = 1.96$.
